## Factor of IID for the Ising model on

the tree

Allan Sly and Lingfu Zhang (Princeton)
February 2021
Joint work with
Danny Nam (Princeton)

## Local Functions

Two perspectives:

Local functions for optimization
Factors of IID - Ergodic Theory

## Large Independent sets

Finding large independent sets in d-random regular graphs.

Largest IS is roughly $\frac{(2+o(1)) \log d}{d} \mathrm{n}$.
Lauer and Wormald '07 give a local algorithm that finds an IS of size $\frac{(1+o(1)) \log d}{d} n$

Iteratively pick vertices with probability $p$ and add them to the set if possible.

Gap of factor of 2 .

## Large Independent sets

Hatami, Lovasz, and Szegedy asked if there were local algorithms up to $\frac{(2-\epsilon) \log d}{d}$

No for IS up to $\frac{\left(1+\frac{1}{\sqrt{2}} o(1)\right) \log d}{d} n$ Gamarnik, Sudan ' 14 Independent sets larger than $\frac{(1+\epsilon) \log d}{d} n$ come in well separated clusters.

No for IS larger than $\frac{(1+\epsilon) \log d}{d} n$ Rahman, Virag ' 17

## Factors of IID

Goal:reconstruct $\sigma: V \rightarrow X$ e.g. colouring, matching, Ising from IID random variables $\left\{U_{x}\right\}_{x \in V}$.
On a transitive graph e.g. $\mathbb{Z}^{d}, \mathbb{T}^{d}$ with randomness a FIID is a measurable function

$$
f:[0,1]^{V} \rightarrow X, \quad \sigma(x)=f\left(\tau_{x}\left\{U_{y}\right\}\right),
$$

where $\tau_{x}$ is the shift operator $\left(\tau_{x}\{U\}\right)_{z}=U_{z-x}$.
Note that there is no assumption on the radius but by measurability it can be approximated by bounded radius.

On $\mathbb{Z}^{d}$ being a factor of IID is equivalent to being isomorphic to a Bernoulli shift.

## Factors of IID

> Matchings
> Holroyd, Pemantle, Peres, Schramm '09

Divide and Colour
Partition vertices and colour components independently e.g. Ising, Potts, Voter Voter stationary distribution S., Zhang '19

## Ising model on trees (Free measure)

A random assignment

$\sigma \in\{-1,+1\}^{V}$

with distribution

$$
\mathbb{P}[\sigma]=\frac{1}{Z} \exp \left(\beta \sum_{u \sim v} \sigma_{u} \sigma_{v}\right)
$$

Alternatively: a broadcast model where a vertex is equal to its parent with probability

$$
\frac{1}{2}+\frac{1}{2} \tanh \beta
$$

$\operatorname{Cov}\left(\sigma_{u}, \sigma_{v}\right)=(\tanh \beta)^{d(u, v)}$

FK model: $\xi \in\{0,1\}^{E}$

$$
\mathbb{P}[\xi]=\frac{1}{Z} y^{\Sigma \xi_{u}} 2^{\# C(\xi)}
$$

where $C(\xi)$ is number of connected components.
On tree percolation w.p.

$$
p=\tanh \beta
$$

## Phase Transitions (Uniqueness)

Uniqueness Threshold: $\tanh \beta=d^{-1}$

The critical value for a distant boundary to effect the root

$$
\lim _{\ell} \mathbb{P}\left[\sigma_{\rho}=+\mid \sigma_{S_{\ell}} \equiv+\right]=1 / 2 \Leftrightarrow \tanh \beta \leq d^{-1}
$$

For larger $\beta$ there exist multiple Gibbs measures (extensions to infinite graph) such as the plus measure.

High Temperature: $\tanh \beta \leq d^{-1}$ FK - model $p \leq d^{-1}$ so all components are finite.
There exists a FIID.

## Phase Transitions (Reconstruction)

Reconstruction/Extremeality Threshold: $\tanh \beta=d^{-1 / 2}$ Critical value for distant vertices to affect the root.

$$
\lim _{\ell} \mathbb{P}\left[\sigma_{\rho}=+\mid \sigma_{S_{\ell}}\right]=1 / 2 \text { a.s. } \Leftrightarrow \tanh \beta \leq d^{-1 / 2}
$$

## Low Temperature $\tanh \beta>d^{-1 / 2}$

Distant spins contain information about the root, +-++-

$$
\operatorname{Var}\left((d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}\right) \rightarrow C
$$

$\lim _{\ell} \operatorname{Cov}\left(\sigma_{\rho},(d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}\right)>0$
Is FIID possible with such long range dependencies?

## No FIID for low temperature.

Suppōse $\sigma_{x}=f\left(\tau_{x}(\{U\})\right)$
There exists a finite range factor $g$ such that
$\sigma_{x}^{\prime}=g\left(\tau_{x}(\{U\})\right) \in\{-1,1\}, \quad \mathbb{P}\left[\sigma_{x}^{\prime} \neq \sigma_{x}\right] \leq \epsilon, \quad \mathbb{E}\left[\sigma_{x}^{\prime}\right]=0$
Then we have

$$
\lim _{\ell} \operatorname{Cov}\left(\sigma_{\rho}^{\prime},(d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}\right)>0
$$

By symmetry
$\operatorname{Cov}\left(\sigma_{\rho}^{\prime},(d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}\right)=\operatorname{Cov}\left(\sigma_{\rho},(d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}^{\prime}\right)$ But
$\operatorname{Var}\left((d \tanh \beta)^{-\ell} \Sigma_{u \in S_{\ell}} \sigma_{u}^{\prime}\right) \leq(d \tanh \beta)^{-2 \ell} * C d^{\ell} \rightarrow 0$ since $\sigma_{u}^{\prime}$ are uncorrelated at large distances.

## Intermediate temperatures?

Lyons 14 asked, when $\tanh \beta \in\left(d^{-1}, d^{-1 / 2}\right)$ is there a factor of IID?
Attempt 1: In the FK model, the components are infinite - no translation invariant way to assign the colours.

Attempt 2: Peres suggest the following:
Construct $\sigma$ using the Glauber Dynamics Markov chain.
Each vertex has rate 1 Poisson clock
Update it according to stationary distribution.
Use coupling from the past i.e. run for $t \in(-\infty . .0]$
Different initial condition such as + lead to different
Gibbs measures.
Suggests IID initial configuration.
Simulations/heuristics suggest it does not converge almost surely.

## Intermediate temperatures?

Attempt 3: Assign the vertices in order.
There's no T.I. ordering of all the vertices.
But we can assign them times $T_{v} \in[0,1]$ IID plus $U_{v} \in[0,1]$
Set $\sigma_{v}=1$ if $U_{v} \leq \mathbb{P}\left[\sigma_{v}=1 \mid\left\{\sigma_{u}\right\}_{u: T_{u}<T_{v}}\right]$
Problem: There exist multiple solution given $\left\{U_{v}, T_{v}\right\}_{v \in V}$. Difficult to control the effect of far away choices.

Attempt 4: Reveal noisy version of $\sigma_{v}, H_{v, 1}, H_{v, 2}, \ldots$ at times $T_{v, i}$ where $\mathbb{P}\left[\sigma_{v}=H_{v, i}\right]=1 / 2+\alpha$.

Then $\mathrm{X}_{\mathrm{v}}(\mathrm{n}):=\sum_{i=1}^{n} H_{v, i} \approx N\left(2 \alpha \sigma_{v} n, n\right)$.
Still requires hard choices - idea take $\alpha \rightarrow 0$. Asymptotically $\mathrm{X}_{\mathrm{v}}(\mathrm{n})$ is Brownian motion with drift.

## FIID Construction

We will build a process $X_{t}(v)=\sigma_{v} t+B_{t}(v)$ where $B_{t}(v)$ are independent Brownian motions.

Easy to construct if we already know $\sigma_{v}$ (but we don't).

Easier example: single vertex $v$. Then if $\mathcal{F}_{t}$ is the filtration generated by $X_{t}$ then

$$
\mathbb{E}\left[\sigma_{v} \mid \mathcal{F}_{t}\right]=\tanh X_{t}(v)
$$

we have can construct it by

$$
d X_{t}(v)=\tanh X_{t}(v) d t+d B_{t}(v)
$$

The stochastic differential equation has a unique strong solution, that is we can construct $X_{t}(v)$ given $B_{t}(v)$.

## FIID Construction

For all $v$ we want to construct $X_{v}(t)$ simultaneously.

The Ising model with external field $\left\{h_{v}\right\}$ is given by

$$
\mathbb{P}_{h}[\sigma]=\frac{1}{Z} \exp \left(\beta \sum_{u \sim v} \sigma_{u} \sigma_{v}+\sum_{v} h_{v} \sigma_{v}\right)
$$

Then by Bayes rule with $\mathcal{F}_{t}=\left\{X_{s}(v)\right\}_{s \leq t, v \in T}$

$$
\mathbb{E}\left[\sigma_{v} \mid \mathcal{F}_{t}\right]=\mathbb{E}_{X_{t}}\left[\sigma_{v}\right]
$$

And $X_{t}(v)$ is a solution of

$$
d X_{t}(v)=\mathbb{E}_{X_{t}}\left[\sigma_{v}\right] \mathrm{dt}+d B_{t}(v)
$$

This is an infinite dimensional SDE.
It has multiple strong solutions.
Theorem (Nam, S., Z.) When $\tanh \beta \in\left(d^{-1}, \delta d^{-\frac{1}{2}}\right)$ there is a strong solution that gives a FIID for the free Ising model.

## FIID Construction

For the infinite dimensional SDE

$$
d X_{t}(v)=\mathbb{E}_{X_{t}}\left[\sigma_{v}\right] \mathrm{dt}+d B_{t}(v)
$$

We now construct a strong solution that is translation invariant; i.e., define a translation invariant function $\mathcal{F}: B \mapsto X$.

A step back: on a finite graph, this SDE has a unique strong solution. On a ball of radius $R$ around the root $\rho\left(T_{R}\right)$ we build the SDE

$$
d X_{t}^{R}(v)=\mathbb{E}_{X_{t}^{R}}\left[\sigma_{v}\right] \mathrm{dt}+d B_{t}(v) \quad \forall v \in T_{R}
$$

Theorem (Nam, S., Z.)
When $\tanh \beta \in\left(d^{-1}, \delta d^{-\frac{1}{2}}\right)$, almost surely as $R \rightarrow \infty$

$$
X_{t}^{R}(v) \rightarrow X_{t}(v)
$$

And the limit $X_{t}(v)$ is independent of the choice of $\rho$.

## Comparing $X_{t}^{R}$ and $X_{t}^{R+1}$

To show convergence, bound the difference between $X_{t}^{R}$ and $X_{t}^{R+1}$. Again we take a continuous approach.
For $\gamma \in[0, \beta]$ define

$$
\mathbb{P}_{h, \gamma}[\sigma]=\frac{1}{Z} \exp \left(\beta \sum_{\substack{u \sim v \\ u, v \in T_{R}}} \sigma_{u} \sigma_{v}+\gamma \sum_{\substack{u v v \\ u \in T_{R}, v \in T_{R+1}}} \sigma_{u} \sigma_{v}+\sum_{v \in T_{R+1}} h_{v} \sigma_{v}\right)
$$

In words, it is Ising model on $T_{R+1}$ with external field $h\left(\mathbb{P}_{h}\right)$, and the inverse temperature on leaves is $\gamma$ instead of $\beta$.
Let $X_{t}^{R, \gamma}$ be the solution of

$$
d X_{t}^{R, \gamma}(v)=\mathbb{E}_{X_{t}^{R, \gamma}, \gamma}\left[\sigma_{v}\right] \mathrm{dt}+d B_{t}(v)
$$

By varying $\gamma$ we interpolate:
$X_{t}^{R, 0}=X_{t}^{R}$ and $X_{t}^{R, \beta}=X_{t}^{R+1}$

## Comparing $X_{t}^{R}$ and $X_{t}^{R+1}$

Denote $H_{t}^{R, \gamma}=\frac{d}{d \gamma} X_{t}^{R, \gamma}$.
From $d X_{t}^{R, \gamma}(v)=\mathbb{E}_{X_{t}^{R, \gamma}, \gamma}\left[\sigma_{v}\right] \mathrm{dt}+d B_{t}(v)$ we compute that $\frac{d}{d t} H_{t}^{R, \gamma}(v)=\partial_{\gamma} \mathbb{E}_{\lambda_{t}^{R, \gamma}, \gamma}\left[\sigma_{v}\right]=M_{t} H_{t}^{R, \gamma}(v)+N_{t}(v)$
where $M_{t}$ is a $T_{R+1} \times T_{R+1}$ matrix: $M_{t}(u, v)=\operatorname{Cov}_{X_{t}^{R, v}}\left(\sigma_{u}, \sigma_{v}\right)$, and $N_{t}(v)=\sum_{u \in T_{R}, u \sim u^{\prime}, u^{\prime} \in \partial T_{R+1}} \operatorname{Cov}_{X_{t}^{R, v}}\left(\sigma_{v}, \sigma_{u} \sigma_{u^{\prime}}\right)$

Thus we can write

$$
H_{t}^{R, \gamma}=\sum_{k=1}^{\infty} \int_{0<t_{1}<\cdots<t_{k}<t} M_{t_{k}} \ldots M_{t_{2}} N_{t_{1}} d t_{1} \ldots d t_{k}
$$

## Comparing $X_{t}^{R}$ and $X_{t}^{R+1}$

To bound $X_{t}^{R}-X_{t}^{R+1}$, we study the second moment $\mathbb{E}\left[\left(H_{t}(v)\right)^{2}\right]$.
From $H_{t}=\sum_{k=1}^{\infty} \int_{0<t_{1}<\cdots<t_{k}<t} M_{t_{k}} \ldots M_{t_{2}} N_{t_{1}} d t_{1} \ldots d t_{k}$, we can write $\left(H_{t}(v)\right)^{2}$ as sum and integral of terms like
$\operatorname{Cov}_{X_{t_{0}}}\left(\sigma_{v_{1}}, \sigma_{v_{0}} \sigma_{v_{0}^{\prime}}\right) \operatorname{Cov}_{X_{t_{k}}}\left(\sigma_{v_{k}}, \sigma_{v_{k+1}} \sigma_{v_{k+1}^{\prime}}\right)$

$$
\times \prod_{i=1}^{k-1} \operatorname{Cov}_{X_{t_{i}}}\left(\sigma_{v_{i}}, \sigma_{v_{i+1}}\right)
$$

where $v \in\left\{v_{0}, \ldots, v_{k+1}\right\}$,

and $v_{0}, v_{k+1} \in T_{R}, v_{0} \sim v_{0}^{\prime}, v_{k+1} \sim v_{k+1}^{\prime}$, and $v_{0}^{\prime}, v_{k+1}^{\prime} \in \partial T_{R+1}$

## Comparing $X_{t}^{R}$ and $X_{t}^{R+1}$

$\operatorname{Cov}_{X_{t_{0}}}\left(\sigma_{v_{1}}, \sigma_{v_{0}} \sigma_{v_{0}^{\prime}}\right) \operatorname{Cov}_{X_{t_{k}}}\left(\sigma_{v_{k^{\prime}}}, \sigma_{v_{k+1}} \sigma_{v_{k+1}^{\prime}}\right) \prod_{i=1}^{k-1} \operatorname{Cov}_{X_{t_{i}}}\left(\sigma_{v_{i}} \sigma_{v_{i+1}}\right)$ where $v \in\left\{v_{0}, \ldots, v_{k+1}\right\}$, and $v_{0}, v_{k+1} \in T_{R}, v_{0} \sim v_{0}^{\prime}, v_{k+1} \sim v_{k+1}^{\prime}$, and $v_{0}^{\prime}, v_{k+1}^{\prime} \in \partial T_{R+1}$

Given $v$, we wish the sum (and integral) of all such terms decay fast in $R$ (want $\sum_{R}\left|X_{t}^{R}(v)-X_{t}^{R+1}(v)\right|<\infty$ a.s.).
A direct bound: in a tree, external fields only decrease covariances:

$$
0 \leq \operatorname{Cov}_{h}\left(\sigma_{v}, \sigma_{u}\right) \leq \operatorname{Cov}_{0}\left(\sigma_{v}, \sigma_{u}\right)
$$

$=(\tanh \beta)^{\operatorname{dist}(u, v)}<d^{-\operatorname{dist}(u, v) / 2}$
(recall $\tanh \beta<\delta d^{-\frac{1}{2}}$ ).

A bound of $(\tanh \beta)^{\operatorname{dist}\left(v_{0}, v_{1}\right)+\cdots+\operatorname{dist}\left(v_{k}, v_{k+1}\right)}$ is not enough!
e.g. $\sum_{v_{0}, v_{2} \in \partial T_{R}} d^{-\left(\operatorname{dist}\left(v_{0}, v\right)+\operatorname{dist}\left(v, v_{2}\right)\right) / 2} \approx d^{R}$.

## Comparing $X_{t}^{R}$ and $X_{t}^{R+1}$

$\operatorname{Cov}_{X_{t_{0}}}\left(\sigma_{v_{1}}, \sigma_{v_{0}} \sigma_{v_{0}^{\prime}}\right) \operatorname{Cov}_{X_{t_{k}}}\left(\sigma_{v_{k}}, \sigma_{v_{k+1}} \sigma_{v_{k+1}^{\prime}}\right) \prod_{i=1}^{k-1} \operatorname{Cov}_{X_{t_{i}}}\left(\sigma_{v_{i}}, \sigma_{v_{i+1}}\right)$ where $v \in\left\{v_{0}, \ldots, v_{k+1}\right\}$, and $v_{0}, v_{k+1} \in T_{R}, v_{0} \sim v_{0}^{\prime}, v_{k+1} \sim v_{k+1}^{\prime}$, and $v_{0}^{\prime}, v_{k+1}^{\prime} \in \partial T_{R+1}$
A bound of $(\tanh \beta)^{\operatorname{dist}\left(v_{0}, v_{1}\right)+\cdots+\operatorname{dist}\left(v_{k}, v_{k+1}\right)}$ is not enough!
e.g. $\sum_{v_{0}, v_{2} \in \partial T_{R+1}} d^{-\left(\operatorname{dist}\left(v_{0}, v\right)+\operatorname{dist}\left(v, v_{2}\right)\right) / 2} \approx d^{R}$.

Suffices to have one extra factor:
$\frac{1}{k!}(\tanh \beta)^{\operatorname{dist}\left(v_{0}, v_{1}\right)+\cdots+\operatorname{dist}\left(v_{k}, v_{k+1}\right)+\operatorname{dist}\left(v_{k+1}, v_{0}\right)}$
Each $(\tanh \beta)^{L}$ corresponds to a walk starting and ending at $v$ with length $L$; there are $\approx(d+o(1))^{L / 2}$ such walks.

Or the prob of a random walk starting from $v$. At each step, with prob $1 / 2$ moves farther from $v$, and prob $1 / 2$ moves closer to $v$.

$$
\begin{aligned}
& \text { Estimating } \mathbb{E}\left[\left(H_{t}^{R, \gamma}(v)\right)^{2}\right] \\
& \mathbb{E}\left[\operatorname{Cov}_{X_{t_{0}}^{R, \gamma}}\left(\sigma_{v_{1}}, \sigma_{v_{0}} \sigma_{v_{0}^{\prime}}\right) \operatorname{Cov}_{X_{t_{k}}^{R, \gamma}}\left(\sigma_{v_{k}}, \sigma_{v_{k+1}} \sigma_{v_{k+1}^{\prime}}\right) \prod_{i=1}^{k-1} \operatorname{Cov}_{X_{t_{i}}^{R, \gamma}}\left(\sigma_{v_{i}}, \sigma_{v_{i+1}}\right)\right] \\
& <(C \tanh \beta)^{\operatorname{dist}\left(v_{0}, v_{1}\right)+\cdots+\operatorname{dist}\left(v_{k}, v_{k+1}\right)+\operatorname{dist}\left(v_{k+1}, v_{0}\right)}
\end{aligned}
$$

## Actually we can write

$\operatorname{Cov}_{X_{t}}\left(\sigma_{v}, \sigma_{u} \sigma_{u^{\prime}}\right)=\frac{\sinh \left(X_{t}\left(u^{\prime}\right)\right)(\tanh \beta)^{\operatorname{dist}\left(u^{\prime}, v\right)}}{2\left(\bar{Z}_{X_{t}}\left(u^{\prime}, v\right)\right)^{2}}$
$\operatorname{Cov}_{X_{t}}\left(\sigma_{u}, \sigma_{v}\right)=\frac{(\tanh \beta)^{\operatorname{dist}(u, v)}}{\left(\bar{Z}_{X_{t}}(u, v)\right)^{2}}$
where $\bar{Z}_{X_{t}}(u, v)=\frac{Z_{X_{t}}(u, v)}{Z_{0}(u, v)} \geq 1$

Need: $\mathbb{E}\left[\frac{\sinh \left(X_{t_{0}}\left(v_{0}\right)\right) \sinh \left(X_{t_{k}}\left(v_{k+1}\right)\right)}{\left(\Pi_{i} \bar{Z}_{X_{t}}\left(v_{i}, v_{i+1}\right)\right)^{2}}\right]$

$<(C \tanh \beta)^{\operatorname{dist}\left(v_{k+1}, v_{0}\right)}$

## Estimating $\mathbb{E}\left[\left(H_{t}^{R, \gamma}(v)\right)^{2}\right]$

Need: $\mathbb{E}\left[\frac{\sinh \left(X_{t_{0}}\left(v_{0}\right)\right) \sinh \left(x_{t_{k}}\left(v_{k+1}\right)\right)}{\left(\Pi_{i} \bar{Z}_{X_{t_{i}}}\left(v_{i}, v_{i+1}\right)\right)^{2}}\right]<(C \tanh \beta)^{\operatorname{dist}\left(v_{k+1}, v_{0}\right)}$
The LHS is 'like' $\mathbb{E}\left[\sigma_{v_{0}} \sigma_{v_{k+1}}\right]$, which equals $(\tanh \beta)^{\operatorname{dist}\left(v_{k+1}, v_{0}\right)}$.
However, the weights make it hard to compute directly.
Recall how we compute $\mathbb{E}\left[\sigma_{v_{0}} \sigma_{v_{k+1}}\right]$ : one way is to take the path from $v_{0}$ to $v_{k+1}$, and it is a Markov chain.

Solution: reveal the field gradually

For $0 \leq \ell \leq \operatorname{dist}\left(v_{k+1}, v_{0}\right)$, construct measure $\mu_{ \pm, \ell}$ :

$$
d \mu_{ \pm, \ell}=\frac{I\left( \pm X_{t_{0}}\left(v_{0}\right)>0\right) \sinh \left(\left|X_{t_{0}}\left(v_{0}\right)\right|\right)}{\left(\Pi_{i} \bar{Z}_{X_{t_{i}}}^{(\ell)}\left(v_{i}, v_{i+1}\right)\right)^{2}} d \mu
$$

Where $\bar{X}_{X_{t_{i}}}^{(\ell)}$ is $\bar{Z}_{X_{t_{i}}}$ restricted to $G^{(\ell)}$.
We couple $\mu_{+, \ell}$ with $\mu_{-, \ell}$ inductively (in $\ell$ ), minimizing

$$
\mathbb{E}_{\mu_{+, \ell}}\left[\sinh \left(X_{t_{k}}\left(v_{k+1}\right)\right)\right]-\mathbb{E}_{\mu_{-, \ell}}\left[\sinh \left(X_{t_{k}}\left(v_{k+1}\right)\right)\right]
$$

## Open Problems

Some directly related questions:

1) Extend the analysis to full intermediate regime?

The reason we require tanh $\beta \in\left(d^{-1}, \delta d^{-1 / 2}\right)$ instead of $\tanh \beta \in\left(d^{-1}, d^{-1 / 2}\right)$ is technical, rather than intrinsic.
2) Find a simpler FIID?

Is there a more direct construction, avoiding the computations?
3) What is the relationship between FIIDs and reconstruction/extremality?

## 1RSB models

Several models (colourings, large independent sets, k -sat) are in the one step replica symmetry breaking universality class.

Thresholds

Colouring

IS/Hardcore

$$
\alpha=\frac{\log d}{d}
$$

$\alpha=\frac{\log d}{d}$
$\alpha=\frac{2 \log d}{d}$

## Full RSB models

Example: Sherrington-Kirkpatrick model, antiferromagnetic Ising model.

For spin glasses Subag '18, Montanari '19, El Alaoui, Montanari Selke '20 gave algorithms that give ( $1-\epsilon$ ) approximation to the ground state.

Should also apply to anti-ferromagnetic Ising model:
Max Cut $=\mathrm{n}\left(\frac{d}{2}+\sqrt{d} P_{*}+o(\sqrt{d})\right)$
[Dembo, Montanari, Sen]
The Gibbs measure is not locally optimal.

Thank you for listening
